

INTENSITY INTERFEROMETRY WITH CHERENKOV TELESCOPE ARRAYS Prospects for submilliarcsecond optical imaging Dainis Dravins – Lund Observatory

Proposed kilometric diffraction-limited optical imagers

Kilometric Baseline Space Interferometry Comparison of free-flyer and moon-based versions. Report by the Space Interferometry Study Team, ESA (1996)

NASA Stellar Imager mission concept K.G.Carpenter et al.: http://hires.gsfc.nasa.gov/si/

KEOPS optical array at Concordia Base in Antarctica (Vakili et al : FAS Publ. Ser. 14, 211, 2005)

A many-mirror hypertelescope operates like a giant diluted telescope (Labeyrie et al., Exp.Astron. 23, 463, 2009)

With telescopes distributed over a few km², the *Cherenkov Telescope Array* can operate as a kilometric optical intensity interferometer to achieve diffraction-limited imaging and optical aperture synthesis

http://www.cta-observatory.org/

Air Cherenkov Telescopes

- The charged particles in the shower are moving faster than the speed of light in air (=c/n)
- A moving charge causes atoms in the atmosphere to become polarised and emit light

A fast particle causes a cone shaped "shock wave" -The emission forms a coherent wavefront at the Cherenkov angle $\cos \theta = 1/\beta n$ (~1.3° in air)

Aharonian et al.,: *Primary particle acceleration above 100 TeV in the shell-type supernova remnant RX J1713.7-3946 with deep HESS observations*, A&A 464, 235

The High Altitude Gamma Ray Telescope (HAGAR), Hanle, Ladakh, India The Indian Astronomical Observatory, world's highest major optical observatory is in the western Himalayas, 4,517 m above sea level in the village of Hanle. Photo by Prabhu B. Doss

B.S. Acharya et al. (988 co-authors!): Introducing the CTA concept, Astropart. Phys. 43, 3 (2013)

CTA telescope concepts

Left: Baseline design for a large telescope of 23 m diameter, with 4.5° field of view and 2500 pixels of 0.1° diameter.

Center: Baseline design for the 12 m diameter medium-sized telescope of Davies–Cotton optical design (spherical primary), with 8° FoV and 1500 pixels of 0.18°.

Right: Design for a Schwarzschild–Couder dual-mirror telescope, with a compact camera close to the secondary mirror. It will have a FoV of 8° diameter, consisting of 11000 square pixels of 0.067° side length.

R.Hanbury Brown: The Stellar Interferometer at Narrabri Observatory Sky and Telescope 28, No.2, 64, August 1964

Intensity interferometry ... the early days

Narrabri observatory with its circular railway track R. Hanbury Brown: BOFFIN. A Personal Story of the Early Days of Radar, Radio Astronomy and Quantum Optics (1991)

INTENSITY INTERFEROMETRY

D.Dravins, S.LeBohec, H.Jensen, P.D.Nuñez:

Stellar Intensity Interferometry: Prospects for sub-milliarcsecond optical imaging, New Astron. Rev. 56, 143 (2012)

Intensity interferometry

<u>Pro:</u> Time resolution of 10 ns, say, implies 3 m light travel time; no need for more accurate optics nor atmosphere. Short wavelengths no problem; hot sources observable

<u>Con:</u> Signal comes from two-photon correlations, increases as signal squared.

Realistic time resolutions require high photometric precision, therefore large flux collectors.

John Davis & Robert Hanbury Brown with model of a proposed very large stellar intensity interferometer with 12 m flux collectors, spanning a 2 km baseline R.Hanbury Brown: BOFFIN. A Personal Story of the Early Days of Radar, Radio Astronomy and Quantum Optics (1991)

Software telescopes in radio and the optical Sofar

LOFAR low-band antennas at Onsala Space Observatory

Low-frequency radio waves, ~100 MHz

Many antennas, huge data flows. Radio-wave amplitude sampled 12 bits deep. Spectral resolution ~1 kHz, bandwidth 32 MHz. Measures first-order coherence. Large, central on-line data processing facility.

Optical Intensity Interferometer

Low-frequency optical fluctuations, ~100 MHz

Many telescopes, moderate data flows. Photon counts recorded (1 bit). Spectral resolution by optical filters. Measures second-order coherence. On-line or off-line data processing.

Center column: (u, v)-plane coverage for a star in zenith. Right: (u, v)-plane coverage for a star moving from zenith through 20 degrees west.

Many telescopes combined in software 'fully' cover the interferometric (u,v)-plane

Digital intensity interferometry * Cherenkov telescopes: Large flux collectors * Fast digital detectors & high-speed signal handling * Combine optical telescopes in software * Huge number of baselines, no loss of digital signal * Example: 65 telescopes: N×(N-1)/2 = 2080 baselines * Filled (u,v)-plane enables sub-milliarcsecond imaging

S/N in intensity interferometry

PROPORTIONAL TO:

- * Telescope areas (geometric mean)
- ***** Detector quantum efficiency
- * Square root of integration time
- ***** Square root of electronic bandwidth
- * Photon flux per optical frequency bandwidth

SIMULATED OBSERVATIONS IN INTENSITY INTERFEROMETRY

Squared visibility ("diffraction pattern"), of a stellar disk of angular diameter 0.5 mas. Z = normalized second-order coherence

Simulated observations in intensity interferometry

Squared visibility from a close binary star. Left: Pristine image; Right: Logarithm of magnitude of Fourier transform

Simulated observations in intensity interferometry

Limiting magnitude for CTA with foreseen instrumentation

Simulated observations of binary stars of visual magnitudes 3, 5, and 7. Total integration time: 20 hours; λ 500 nm, time resolution 1 ns, quantum efficiency = 70% Array: CTA D

SIMULATED OBSERVATIONS IN INTENSITY INTERFEROMETRY

Verification of simulation software against classical observations by Hanbury Brown et al.

Left: Sirius observed with the Narrabri stellar interferometer (R.Hanbury Brown, J.Davis, R.J.W.Lake & R.J.Thompson; MNRAS 167, 475, 1974) Right: Simulated observations with Narrabri instrumental parameters

Simulated observations of binary stars with different sizes. (m_V = 3; T_{eff} = 7000 K; T = 10 h; Δt = 1 ns; λ = 500 nm; Δλ = 1 nm; QE = 70%, array = CTA B) Top: Reconstructed and pristine images; Bottom: Fourier magnitudes. Already changes in stellar radii by only a few micro-arcseconds are well resolved.

D.Dravins, S.LeBohec, H.Jensen, P.D.Nuñez:, CTA Consortium Optical intensity interferometry with the Cherenkov Telescope Array, Astropart. Phys. **43**, 331 (2013)

Simulated observations in intensity interferometry

S/N independent of spectral passband

SIMULATED OBSERVATIONS OF ROTATIONALLY FLATTENED STAR WITH EMISSION-LINE DISK

Left: Pristine image, 0.4 mas across with 10 μ as equatorial emission-line disk, 6 times continuum intensity

Center: Observed magnitude of the Fourier transform in continuum light

Right: Same for a narrow-bandpass filter at He I λ 587 nm emission

Stellar magnitude: $m_v = 6$, $T_{eff} = 7000$ K; T = 50 h, QE=70%; Array = CTA I

Image reconstruction Second-order coherence g⁽²⁾ $q^{(2)}(\tau) = 1 + |q^{(1)}(\tau)|^2$ Does not retain phase information, direct image reconstruction not possible. Imaging requires retrieval of Fourier phases from amplitudes. Feasible if dense coverage of (u,v)-plane

Image reconstruction from intensity interferometry

Numerical simulations of intensity-interferometry observations with a CTA-like array, with image reconstruction of a star with three hotspots

Pristine image has T = 6000 K; spots have 6500K (top-right and left) and 6800K. Simulated data correspond to visual magnitude m_v = 3, and 10 hours of observation.

P.D.Nuñez, R.Holmes, D.Kieda, J.Rou, S.LeBohec, *Imaging submilliarcsecond stellar features with intensity interferometry using air Cherenkov telescope arrays*, MNRAS **424**, 1006 (2012)

NON-RADIAL PULSATIONS & VELOCITIES ACROSS STELLAR SURFACES

Observations through very narrow bandpass filters, spanning one spectral line (might require ordinary telescopes rather than Cherenkov ones)

Simulated observations of a Cepheid-like star undergoing non-radial pulsations $m_V = 3.4$; $T_{eff} = 7000$ K; $\Delta t = 1$ ns; $\lambda = 500$ nm; Array = CTA B Left: Pristine image; Right: Observed Fourier magnitude Kilometer-scale diffraction-limited optical imager: *Cherenkov Telescope Array* as an Intensity Interferometer *Expected resolution for assumed exoplanet transit across the disk of Sirius*

Stellar diameter = 1.7 solar Distance = 2.6 pc Angular diameter = 6 mas

Assumed Jupiter-size planet with rings; four Earth-size moons; equatorial diameter = 350 µas.

CTA array spanning 2 km; Resolution 50 μas at λ 400 nm provides more than 100 pixels across the stellar diameter

Photometric precision First-order coherence: $g^{(1)} = 1$ Second-order coherence for chaotic light: $q^{(2)}(\tau) = 1 + |q^{(1)}(\tau)|^2 = 1 + 1 = 2$

But... experimental $\Delta t \gg$ coherence time τ_c (10 fs?)

Realistic time resolution = 10 ns (?) $q^{(2)}(\tau) = 1 + \varepsilon = 1.00001$ (?)

Understanding detectors

Afterpulsing, afterglow and other detector signatures can mimic intensity correlations

Analyzing photon-counting detectors

Afterpulsing, afterglow and other signatures could mimic intensity correlations

Single-photon-counting avalanche photodiode detectors being evaluated @ Lund Observatory for digital intensity interferometry (made by: ID Quantique; Micro Photon Devices; PerkinElmer; SensL)

Real-time digital photon correlators

Permit to verify various observational modes, both in the lab, and at telescopes

AAAAAAAAAAAA

ALMA correlator

Very much more modest computations than in radio interferometry!

Real-time correlation

Pro: Search all timescales in real time, store only reduced data

Con: Lose information on transients, no alternative analyses

Stellar Intensity Interferometry Laboratory experiments @ Lund Observatory

An artificial star is observed by a pair of movable telescopes. Detected photon streams are cross correlated in real time.

Stellar Intensity Interferometry Laboratory experiments @ Lund Observatory

Artificial stars are observed by movable telescopes across a long optics lab; photoncounting avalanche photodiodes and on-line digital correlators.

The plot shows the measured and expected second-order coherence for two "stars".

STAR BASE UTAH (near Salt Lake City)

Testbed for intensity interferometry & Cherenkov telescope instrumentation

The StarBase 3 m Cherenkov telescopes are protected by buildings which can be rolled open for observation. The control room is located between the two telescopes.

Stellar Intensity Interferometry

VERITAS upgrade & laboratory experiments @ The University of Utah

The ongoing VERITAS upgrade includes provisions also for intensity interferometry. Here, David Kieda examines correlation functions computed off-line in electronics for real-time digitization and storage of photomultiplier signals. ESO Instrument Studies for OWL and Extremely Large Telescopes (2005)

HIGHEST TIME RESOLUTION, REACHING QUANTUM OPTICS

- Other instruments cover seconds and milliseconds
- QuantEYE will cover milli-, micro-, and nanoseconds, down to the quantum limit!

1-

Intensity interferometry can be carried out in moonlight when Cherenkov observations are not feasible E-ELT European Extremely Large Telescope

Mock-up of E-ELT 39.3 m main mirror with 798 hexagons, each 1.4 m wide (ESO's Open House Day in Garching bei München)

Cherenkov telescopes

E-ELT

- \star Huge collecting area, ~ 10,000 m²
- Davies-Cotton telescopes not isochronous, light spread ~ few ns
- ★ Large PSF, ~ few arcmin, PMT's
- Non-collimated light complicates use of color filters
- ★ Separated telescopes, long signal lines, electronic source tracking
- * Limiting magnitude $m_v \sim 8$

- * 40 m $\varnothing \Leftrightarrow$ 64 telescopes of 5 m \varnothing
- ★ Isochronous optics permits very fast detectors down to ~ 10 ps
- ★ Small PSF reduces skylight, enables small solid-state detectors
- ★ Collimated light enables narrow-band filters, multiple spectral bands
- Compact focus, no signal transmission, telescope tracks source
- Limiting magnitude might reach extragalactic sources

Artist's vision image from ESO press release eso1032

E-ELT Adaptive optics @ 2 μm vs. Intensity interferomety @ 400 nm

Small 'technical' instrument (already during E-ELT construction phase?)

* Lenslet array images E-ELT subapertures onto fast photon-counting detectors

* Basically a Shack-Hartmann wavefront sensor

* Electronic signal of photon streams is handled by on-line firmware or off-line software

* Can use incompletely filled aperture, unadjusted mirror segments, poor seeing

* Optical aperture synthesis and diffractionlimited imaging by software!
